

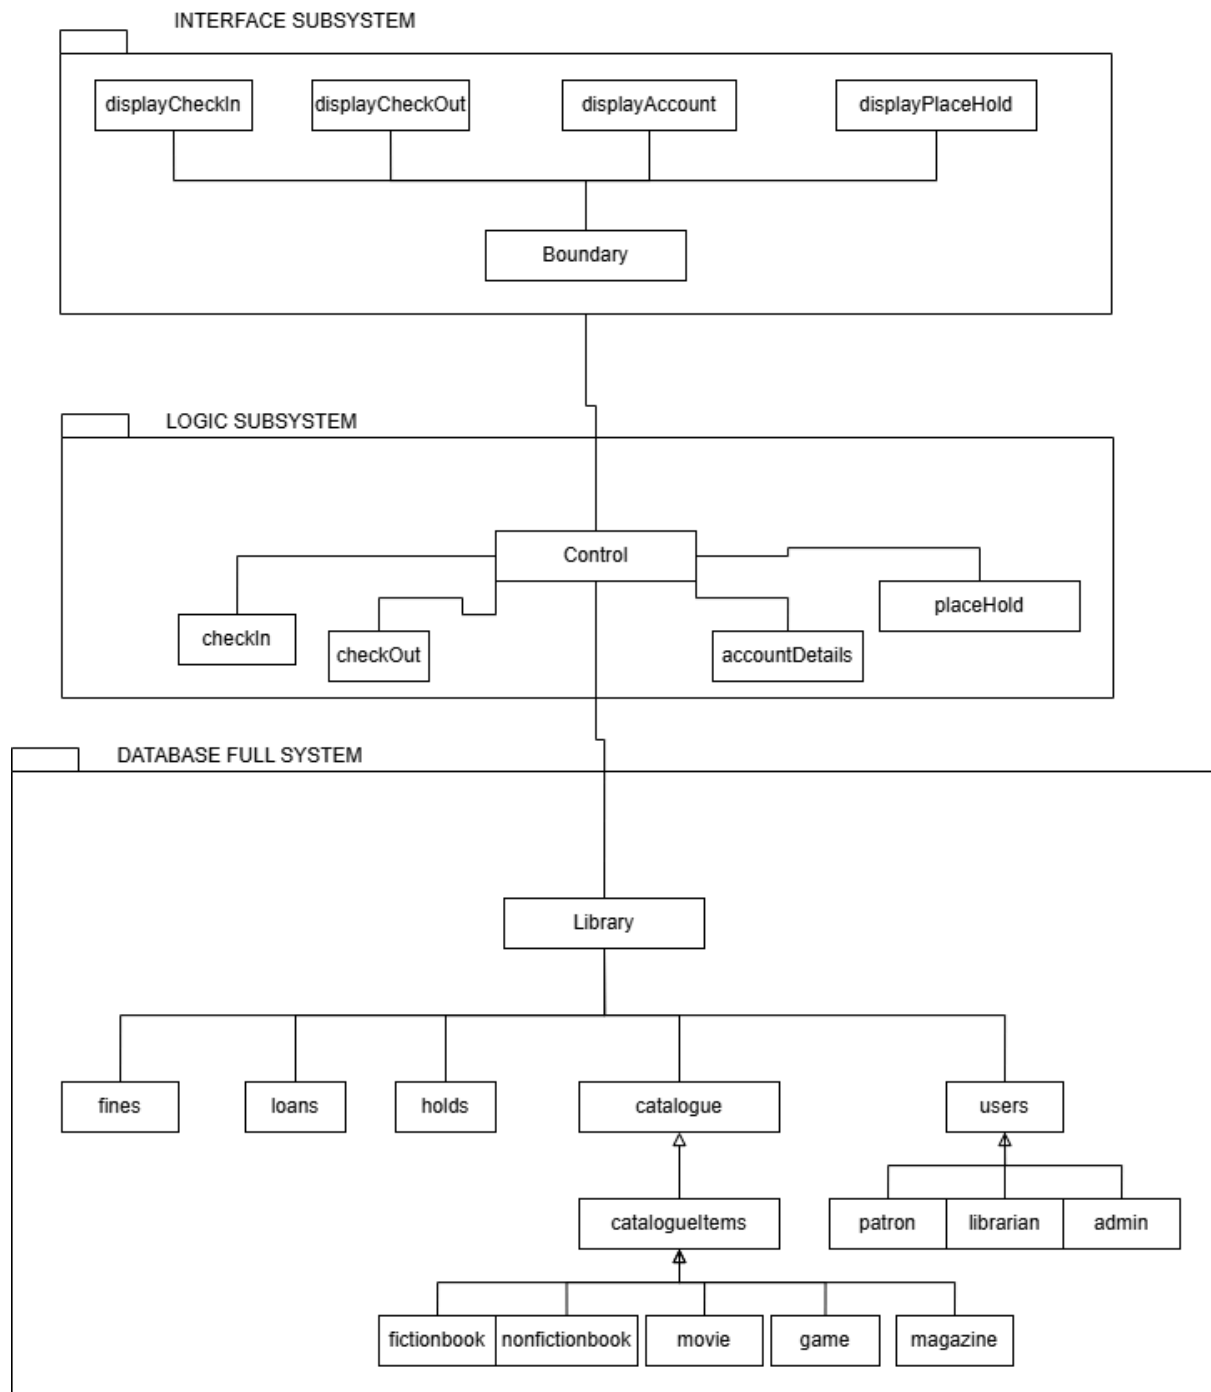

Figure 1: HinLIBS System Decomposition Showing Subsystem Organization and Dependencies

The system minimizes coupling and maximizes cohesion, this is because of the separation of responsibilities. The Library class handles database interaction, the Control class handles business rules and the Boundary Class handles user interaction and display logic. Additionally, each class only interacts with the class below it, so Library and Boundary do not interact and changes in the interface do not require changes in the database. There is also a lot of encapsulation, each part does not need to know how the other functions, meaning that the design can be extended and maintained quite easily.
